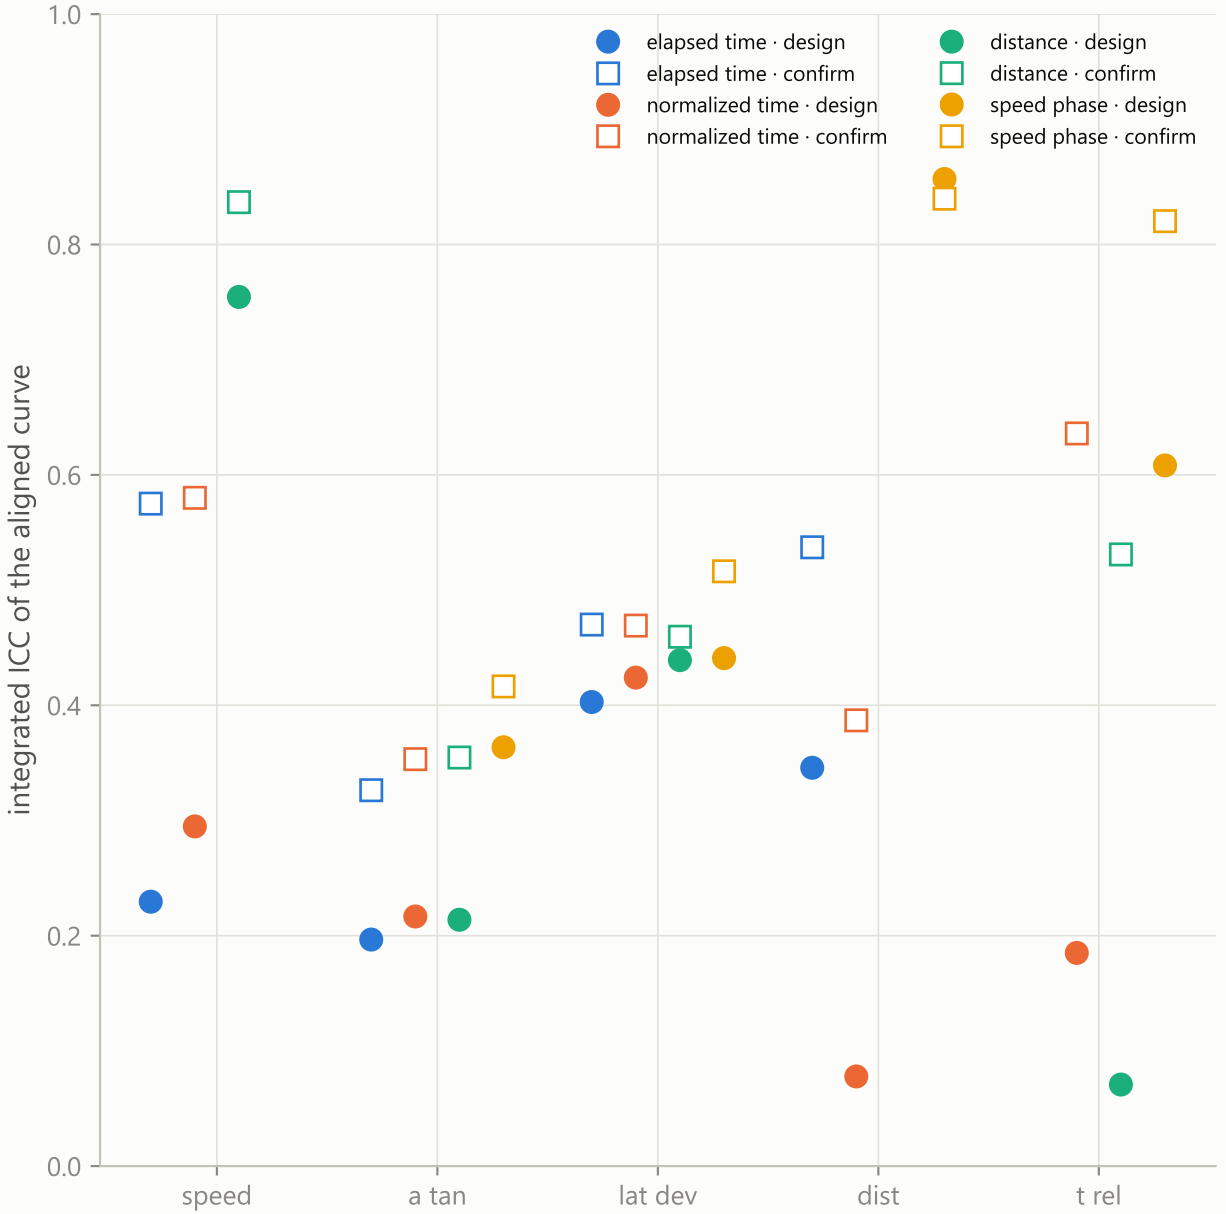
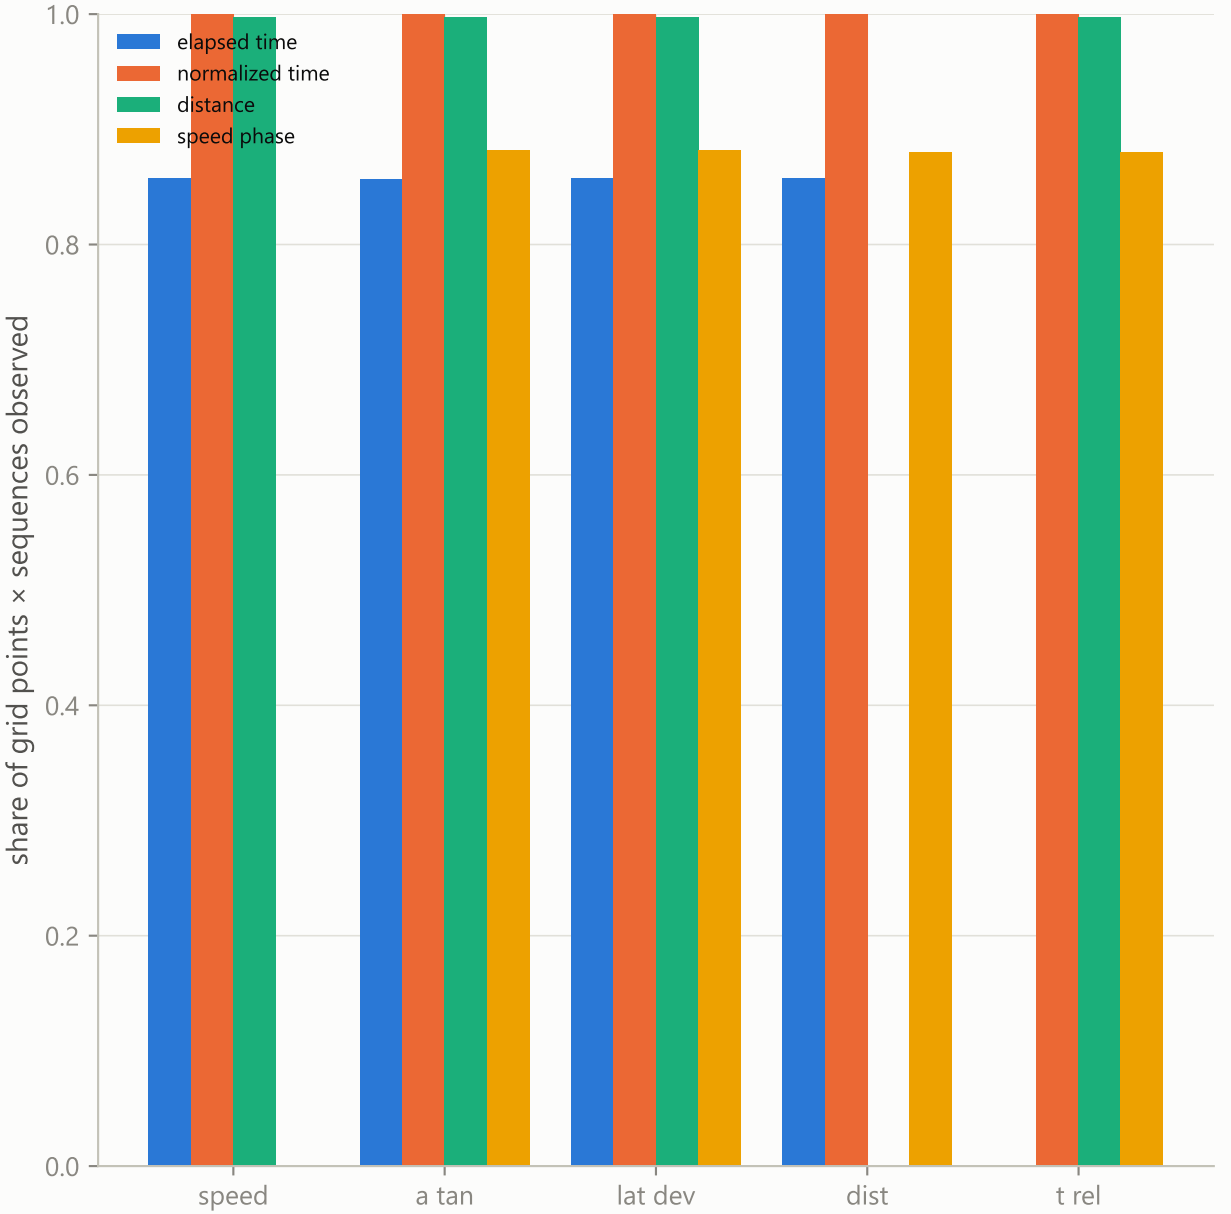
# Which alignment gives repeatable curves?





Unit: athlete with repeated attempts (position adjusted). Left: share of the curve's variance that belongs to the athlete rather than to the attempt; filled = design athletes (decision subset), hollow = the other athletes. Right: how much of each grid the recordings cover. A channel is absent where it is the alignment's own axis. High repeatability is necessary, not sufficient: an alignment can be stable because it removed what distinguishes athletes.
