Position-coach report — Anthony Bradford vs Mason McCormick

OL · Two prospects have similar forty times. What else differs?

Descriptive scouting information from Combine tracking. No value on this page predicts NFL performance: in this project, tracked Combine features did not improve held-out prediction of NFL movement or receiver separation beyond official testing. Use it to decide what to examine next — not to rank prospects.

Observed movement phases

- [Uncertain difference] Initial acceleration: band acceleration 2 → 4 yd/s 4.60 (Anthony Bradford) vs 9.43 (Mason McCormick) yd/s², difference +4.83 [+3.77, +5.89] — inside its measurement uncertainty — not a difference.
- [Measured difference] Early speed development: speed at 10 yd 7.59 (Anthony Bradford) vs 9.10 (Mason McCormick) yd/s, difference +1.51 [+1.23, +1.79] — larger than its measurement uncertainty. On this measure the observed value favours Mason McCormick.
- [Measured difference] Intermediate speed development: band acceleration 6 → 8 yd/s 1.90 (Anthony Bradford) vs 6.05 (Mason McCormick) yd/s², difference +4.15 [+3.39, +4.91] — larger than its measurement uncertainty. On this measure the observed value favours Mason McCormick.
- [Uncertain difference] Late sprint: speed at 30 yd 9.30 (Anthony Bradford) vs 9.23 (Mason McCormick) yd/s, difference -0.07 [-0.24, +0.10] — inside its measurement uncertainty — not a difference.
- [Measured difference] Maximum tracked speed: tracked top speed (p95) 9.34 (Anthony Bradford) vs 9.56 (Mason McCormick) yd/s, difference +0.22 [+0.04, +0.40] — larger than its measurement uncertainty. On this measure the observed value favours Mason McCormick.

Physical demand in games

- [Missing observation] The NFL demand closest to late acceleration and high speed (above about 6 yd/s) ('transition_high'): Too few observed NFL episodes for this position and demand to describe it (support rule of the 09A atlas).
- OL athletes show 81.4 'acceleration from low speed' episodes per 100 eligible player-plays (67,409 episodes, 90 athletes) — the observed game demand physically closest to early acceleration (first steps, below about 4 yd/s).
- OL athletes show 2.7 'acceleration from intermediate speed' episodes per 100 eligible player-plays (2,208 episodes, 83 athletes) — the observed game demand physically closest to mid-sprint speed development (about 4 to 8 yd/s).
- A physical correspondence only: the football advantage of the measured difference has not been established.

Film to cut up

- Film — compare Anthony Bradford and Mason McCormick on screens and long pursuit after a turnover (late acceleration and high speed (above about 6 yd/s)).
- Film — compare Anthony Bradford and Mason McCormick on the first steps of a pull or a set (early acceleration (first steps, below about 4 yd/s)).
- Film — compare Anthony Bradford and Mason McCormick on pulls and climbs to the second level (mid-sprint speed development (about 4 to 8 yd/s)).

Targeted testing

- Late acceleration and high speed (above about 6 yd/s) — a longer sprint or flying 20-yard segment, because 40 yards can end before top speed is reached.
- Early acceleration (first steps, below about 4 yd/s) — timed starts over 0–5 and 0–10 yd with split timing, at least two repetitions, recorded from before the first movement.
- Mid-sprint speed development (about 4 to 8 yd/s) — rolling-start (flying) 10-yard segments entered at a controlled speed, so the 4 → 8 yd/s band is measured directly.

- A proposed test is a candidate way to measure a demand the forty does not describe. Its value for evaluating NFL prospects has not been established and would need prospective evidence.

Limits

- That a physical similarity to an NFL demand means the demand will be met in pads, in traffic or late in a game.
- That a measured Combine difference causes a football outcome, or that training it would change one.
